This guide aims to demystify derivative word problems, providing a comprehensive approach to understanding, solving, and, most importantly, *applying* them. We'll cover strategies, examples, and common pitfalls to help you build confidence and master this crucial aspect of calculus.

Understanding the Fundamentals: Rates of Change

At its core, a derivative represents the instantaneous rate of change of a function. Word problems often involve scenarios where this rate of change is central. For instance, we might need to determine the rate at which a population is growing, the speed of an object, or the marginal cost of producing one more unit of a product. Let's consider a simple example: Problem: A ball is thrown upwards, and its height (in meters) after t seconds is given by the function $h(t) = -5t^2 + 20t$. Find the velocity of the ball after 2 seconds. Solution: 1. Find the derivative: The derivative of $h(t)$ with respect to time (t) represents the velocity, $v(t)$. Therefore, $v(t) = h'(t) = -10t + 20$. 2. Substitute the time: To find the velocity after 2 seconds, substitute $t = 2$ into the velocity function: $v(2) = -10(2) + 20 = 0$ m/s. This shows that after 2 seconds, the ball momentarily stops before falling back down. This seemingly simple problem highlights the power of derivatives in analyzing dynamic situations.

Types of Derivative Word Problems

Derivative word problems aren't monolithic. They encompass various applications, each requiring a slightly different approach:

- **Optimization Problems:** These problems involve finding the maximum or minimum value of a function. Examples include maximizing profit, minimizing cost, or finding the dimensions of a container with maximum volume given a fixed surface area.
- **Related Rates Problems:** These problems involve finding the rate of change of one quantity with respect to the

rate of change of another quantity. Typical scenarios include changing volumes, areas, or distances.

- **Motion Problems:** These problems deal with the position, velocity, and acceleration of moving objects. Understanding the relationship between these three concepts is crucial for solving these problems.
- **Marginal Analysis in Economics:** Derivatives are heavily used in economics to determine marginal cost, marginal revenue, and marginal profit. These concepts help businesses optimize pricing and production strategies.

Related Rates Problems: A Deeper Dive

Related rates problems frequently cause confusion. The key is to identify the relationships between the variables and then use implicit differentiation. Example: **A ladder 10 meters long leans against a vertical wall. The bottom of the ladder slides away from the wall at a rate of 1 m/s. How fast is the top of the ladder sliding down the wall when the bottom of the ladder is 6 meters from the wall?**

Solution: **1.** Diagram: Draw a diagram depicting the ladder, wall, and ground, labeling the relevant lengths and rates. **2.** Relationship: Use the Pythagorean theorem to relate the distance of the bottom of the ladder from the wall (x) and the height of the top of the ladder on the wall (y): $x^2 + y^2 = 10^2$. **3.** Implicit Differentiation: Differentiate both sides of the equation with respect to time (t): $2x(dx/dt) + 2y(dy/dt) = 0$. **4.** Substitute: When $x = 6$, we can find y using the Pythagorean theorem ($y = 8$). We are given $dx/dt = 1$ m/s. Substitute these values into the differentiated equation to solve for dy/dt (the rate at which the top of the ladder is sliding down).

Variable	Value	Units
x (distance from wall)	6 m	meters
y (height on wall)	8 m	meters
dx/dt (rate of change of x)	1 m/s	meters/second
dy/dt (rate of change of y)	-3/4 m/s	meters/second

The negative sign indicates that the height is decreasing.

Optimization Problems: Maximizing and Minimizing

Optimization problems require identifying critical points (where the derivative is zero or undefined) and determining whether these points correspond to a maximum or minimum using the second derivative test. Example: **A farmer wants to fence a rectangular enclosure using 500 meters of fencing. What dimensions maximize the area of the enclosure?**

Solution: **1.** Define Variables: Let x and y represent the length and width of the rectangle. **2.** Constraint: The total fencing is $2x + 2y = 500$. **3.** Objective Function: The area to be maximized is $A = xy$. **4.** Solve for One Variable: Solve the constraint for one variable (e.g., $y = 250 - x$) and substitute into the objective function: $A(x) = x(250 - x) = 250x - x^2$. **5.** Find the Critical Points: Find the derivative $A'(x) = 250 - 2x$ and set it to zero to find the critical point: $x = 125$. **6.** Second Derivative Test: The second derivative $A''(x) = -2$, which is negative, indicating a maximum. **7.**

Solution: The dimensions that maximize the area are $x = 125$ meters and $y = 125$ meters (a square).

This guide is your key to demystifying derivative word problems, breaking down complex scenarios into manageable steps, and equipping you with the tools to find accurate solutions. Get ready to transform those daunting equations into elegant answers!

What Exactly Are Derivatives and Why Do They Matter in Word Problems?

Before we dive headfirst into problem-solving, let's refresh our understanding of what a derivative actually *is*. In its simplest form, the derivative of a function tells us the **instantaneous rate of change** of that function at a specific point. Think of it like looking at a speedometer in your car. It doesn't just tell you how far you've traveled, but how fast you're going *right now*. In the context of word problems, derivatives are invaluable for describing how one quantity changes with respect to another. This could be: **Velocity** as the rate of change of position with respect to time. **Acceleration** as the rate of change of velocity with respect to time. **Marginal cost** as the rate of change of total cost with respect to the number of items produced. **Growth rate** of a population or a tumor. **Rate of cooling** or heating. **Change in volume** as dimensions change. Essentially, whenever a word problem asks about "how fast," "at what rate," "how quickly," or "the speed of change," derivatives are likely your best friend.

The Master Plan: A Step-by-Step Approach to Solving Derivative Word Problems

Tackling derivative word problems effectively requires a structured approach. Trying to jump straight to the calculus can lead to confusion. Here's a proven strategy:

1. Deconstruct the Problem: Read, Re-read, and Visualize

This is arguably the most crucial step. Don't just skim the problem. Read it carefully, multiple times if necessary. As you read, try to: **Identify the unknown:** What is the problem asking you to find? This will be your target variable or quantity. **Identify the knowns:** What information is provided in the problem? Note down all the given values, relationships, and constraints. **Identify the variables:** What quantities are changing? Assign clear and descriptive variable names to these quantities (e.g., t for time, h for

for height, V for volume). * **Visualize the scenario:** Can you sketch a diagram, draw a picture, or create a mental image of the situation? This can help clarify relationships between variables. For instance, if it's about a ladder sliding down a wall, drawing the triangle formed by the wall, the ground, and the ladder is incredibly helpful.

2. Formulate an Equation: The Relationship is Key

Once you understand the components of the problem, you need to translate the given information into a mathematical equation that relates the variables. This might involve: *

Geometric formulas: Area, perimeter, volume formulas for squares, rectangles, circles, spheres, cones, etc. * **Physical principles:** Pythagorean theorem, distance = speed $\times$ time, formulas for motion (if applicable). * **Economic principles:** Cost functions, revenue functions, profit functions. * **General relationships:** Sometimes the relationship is explicitly stated, other times it's implied by the context. This equation will be the foundation upon which you'll build your derivative solution.

3. Differentiate with Respect to the Appropriate Variable

Now it's time for the calculus! You'll differentiate the equation you formulated in step 2. The key here is to differentiate with respect to the variable that represents the **independent change** in the problem. * **Implicit Differentiation:** Most word problems involve related rates, meaning multiple variables are changing simultaneously. You'll likely use implicit differentiation, where you differentiate both sides of your equation with respect to the independent variable (often time, t), remembering to use the chain rule for each variable that depends on t . For example, if you have $V = x^3$, and both V and x are functions of time, differentiating with respect to t gives $\frac{dV}{dt} = 3x^2 \frac{dx}{dt}$. * **Direct Differentiation:** If your equation is already explicitly solved for the variable you're interested in (e.g., $y = f(x)$) and the problem asks for $\frac{dy}{dx}$ (or a similar derivative), you'll perform standard differentiation.

4. Substitute Known Values and Solve

After differentiating, you'll have an equation that relates the rates of change of your variables. Now, you'll substitute in all the *known* values (both for the variables and their rates of change) that are given for the specific moment in time or condition described in the problem. * **Isolate the unknown rate:** Rearrange the equation to solve for the rate you're trying to find. * **Calculate the result:** Perform the necessary arithmetic to arrive at your final answer.

5. Units and Interpretation: Make it Meaningful

Don't forget the units! The units of your answer are crucial for understanding its meaning in the context of the word problem. * **Check your units:** If you're calculating

velocity, your units might be meters per second (m/s) or feet per minute (ft/min). For rates of area change, it might be square inches per second (in²/s). * **Interpret your answer:** Does your answer make sense in the context of the problem? Is it positive or negative, and what does that imply? A negative velocity, for instance, usually means movement in a specific direction (e.g., downwards or leftwards).

Common Types of Derivative Word Problems and Their Solutions

Let's explore some classic scenarios and how to tackle them.

A. Related Rates Problems: The Heart of the Matter

These are the most common type of derivative word problems. They involve two or more quantities that are related by an equation and are changing at different rates. **Example Scenario: Inflating a Balloon** * **Problem:** A spherical balloon is being inflated with air at a rate of 100 cubic centimeters per second. How fast is the radius of the balloon increasing when the radius is 10 centimeters? * **Solution Breakdown:** 1. **Identify:** * Unknown: Rate of change of the radius ($\frac{dr}{dt}$). * Knowns: Rate of change of volume ($\frac{dV}{dt} = 100 \text{ cm}^3/\text{s}$), specific radius ($r = 10 \text{ cm}$). * Variables: Volume (V), radius (r). 2. **Formulate:** The volume of a sphere is $V = \frac{4}{3}\pi r^3$. 3. **Differentiate:** Differentiate both sides with respect to time (t): $\frac{dV}{dt} = \frac{4}{3}\pi (3r^2) \frac{dr}{dt}$ $\frac{dV}{dt} = 4\pi r^2 \frac{dr}{dt}$ 4. **Substitute and Solve:** Plug in the known values: $100 = 4\pi (10)^2 \frac{dr}{dt}$ $100 = 400\pi \frac{dr}{dt}$ $\frac{dr}{dt} = \frac{100}{400\pi} = \frac{1}{4\pi} \text{ cm/s}$ 5. **Units and Interpretation:** The radius is increasing at a rate of $\frac{1}{4\pi}$ centimeters per second when the radius is 10 cm. This positive value makes sense as the balloon is being inflated. **Other Related Rates Examples:** * **Ladder sliding down a wall:** The distance from the wall is changing, the height on the wall is changing, and the ladder's length is constant. * **Water filling a conical tank:** The volume of water, the radius of the water's surface, and the height of the water are all related and changing. * **Car approaching an intersection:** The distance of the car from the intersection and the distance of another car from the intersection are changing, and you might need to find the rate at which the distance between them is changing.

B. Optimization Problems: Finding the Best (or Worst!)

Optimization problems involve finding the maximum or minimum value of a function, often within certain constraints. Derivatives are essential here for finding critical points. **Example Scenario: Maximizing Area with Fixed Perimeter** * **Problem:** A farmer has 100 meters of fencing to enclose a rectangular garden. What are the dimensions of the garden that will maximize its area? * **Solution Breakdown:** 1. **Identify:** *

Unknown: Dimensions of the rectangle (length l , width w) that maximize area. * **Knowns:** Perimeter $P = 100$. * **Variables:** Length (l), width (w), Area (A). 2. **Formulate:** * Perimeter equation: $2l + 2w = 100 \implies l + w = 50 \implies w = 50 - l$. * Area equation (to be maximized): $A = l \times w$. 3. **Substitute to get a function of one variable:** Substitute w from the perimeter equation into the area equation: $A(l) = l(50 - l) = 50l - l^2$. 4. **Differentiate to find critical points:** Find the derivative of $A(l)$ with respect to l : $A'(l) = 50 - 2l$. Set the derivative to zero to find critical points: $50 - 2l = 0 \implies 2l = 50 \implies l = 25$. 5. **Use the Second Derivative Test (or analyze the function):** To confirm it's a maximum, find the second derivative: $A''(l) = -2$. Since the second derivative is negative, this confirms that $l=25$ yields a maximum area. 6. **Find the other dimension and the maximum area:** If $l = 25$, then $w = 50 - 25 = 25$. The maximum area is $A = 25 \times 25 = 625$. 7. **Interpretation:** The garden with the maximum area is a square with sides of 25 meters, yielding an area of 625 square meters. **Other Optimization Examples:** * **Minimizing material for a container:** Finding the dimensions of a can that minimize the amount of metal used for a given volume. * **Maximizing profit:** Finding the production level that yields the highest profit. * **Minimizing travel time:** Finding the shortest route when crossing different terrains with different speeds.

C. Velocity and Acceleration Problems: Motion in Calculus

These problems directly apply the definition of derivatives to motion. * **Position function:** $s(t)$ or $x(t)$ (distance from a reference point at time t). * **Velocity function:** $v(t) = s'(t)$ (the instantaneous rate of change of position). * **Acceleration function:** $a(t) = v'(t) = s''(t)$ (the instantaneous rate of change of velocity). **Example Scenario: Projectile Motion** * **Problem:** The height of a ball thrown vertically upwards is given by the function $h(t) = -16t^2 + 64t + 5$, where h is in feet and t is in seconds. * a) What is the velocity of the ball at time t ? * b) What is the acceleration of the ball at time t ? * c) What is the maximum height the ball reaches? * **Solution Breakdown:** 1. **a) Velocity:** Differentiate the height function $h(t)$ with respect to t : $v(t) = h'(t) = -32t + 64$. 2. **b) Acceleration:** Differentiate the velocity function $v(t)$ with respect to t : $a(t) = v'(t) = -32$. (This is constant acceleration due to gravity). 3. **c) Maximum Height:** The ball reaches its maximum height when its velocity is zero. So, set $v(t) = 0$: $-32t + 64 = 0 \implies 32t = 64 \implies t = 2$. Now, plug this time back into the height function to find the maximum height: $h(2) = -16(2)^2 + 64(2) + 5 = -64 + 128 + 5 = 69$. **### Tips and Tricks for Success** * **Draw Diagrams:** Always! A visual representation can save you a lot of confusion. * **Label Everything:** Clearly label your variables and their units. * **Check for Consistency:** Ensure your units are consistent throughout the problem. * **Read the Question Carefully:** Pay attention to keywords like "increasing," "decreasing," "maximum," "minimum," "rate," "speed." *

Practice, Practice, Practice: The more problems you solve, the more comfortable you'll become with different scenarios and problem-solving techniques. * **Understand the Calculus Concepts:** Don't just memorize formulas. Understand what derivatives represent conceptually. * **Use Online Resources:** Many websites and YouTube channels offer excellent explanations and examples of derivative word problems. ### Conclusion: Conquer Your Derivative Doubts Derivative word problems are a powerful application of calculus that helps us understand and model the real world. Questions & Answers About derivative word problems

and solutions

No	Question	Answer
1	What's the core idea behind using derivatives to solve word problems?	Derivatives help us find the instantaneous rate of change. In word problems, this often translates to finding speeds, acceleration, maximum/minimum values, or how one quantity changes with respect to another.
2	How can derivatives help find the maximum or minimum value of something described in a word problem?	By setting the derivative of the function representing the quantity to zero and solving for the variable. This identifies critical points, which are potential maximums or minimums. Further analysis (like the second derivative test) confirms the nature of these points.
3	I'm struggling with 'related rates' problems. How do derivatives fit in?	Related rates involve quantities that change over time and are dependent on each other. Derivatives are used to find the rate of change of each quantity with respect to time (e.g., dx/dt , dy/dt) and then relate these rates using implicit differentiation.
4	What's an example of a real-world scenario where derivatives are used to solve a word problem?	Optimizing profit for a business. If you have a profit function, its derivative can tell you the production level that maximizes profit.
5	How do I know which function to differentiate in a word problem?	Identify the quantity you're trying to maximize, minimize, or find the rate of change for. That quantity will be your function. The variables in that function will be the ones you differentiate with respect to (often time or another variable in the problem).
6	What's the difference between finding the derivative and interpreting it in a word problem context?	Differentiating is the mathematical process. Interpreting means translating the mathematical result back into the language of the word problem. For example, a derivative of 5 m/s means the object's position is changing at a rate of 5 meters per second.
7	Are there specific keywords in word problems that signal the use of derivatives?	Yes! Look for words like 'rate,' 'speed,' 'velocity,' 'acceleration,' 'change,' 'maximum,' 'minimum,' 'optimize,' 'growing,' or 'decreasing.' These often indicate a need for derivatives.
8	What are some common mistakes students make when solving derivative word problems?	Common mistakes include confusing variables, misinterpreting the question (e.g., finding the function instead of its rate of change), and errors in applying differentiation rules or solving the resulting equations. Careful setup and checking units are crucial.

Mastering Derivative Word Problems: A Comprehensive Guide with Solutions

Unlock the power of calculus by understanding and solving derivative word problems. This in-depth guide will equip you with the strategies and techniques needed to tackle these common challenges, from optimization to rates of change.

Understanding Derivative Word Problems: Bridging Theory and Application

Derivative word problems are the cornerstone of applying calculus to real-world scenarios. They move beyond abstract mathematical symbols and equations, demonstrating how the concept of a derivative – the instantaneous rate of change – can model and predict phenomena in fields like physics, economics, biology, and engineering. At their core, these problems require us to translate a narrative into a mathematical model, identify the relevant rates of change, and then use differentiation techniques to find answers.

The fundamental idea behind any derivative word problem is to find out "how fast" something is changing. This "something" could be the position of a moving object, the cost of producing goods, the population of a species, or the temperature of a substance. The derivative provides the precise mathematical tool to quantify this rate of change at any given moment.

The Essence of Rate of Change

Before diving into specific problem types, it's crucial to solidify the concept of the rate of change. In calculus, the derivative of a function $f(x)$, denoted as $f'(x)$ or dy/dx , represents the slope of the tangent line to the function's graph at a particular point. This slope, in turn, signifies the instantaneous rate at which the dependent variable (y) is changing with respect to the independent variable (x).

Consider a simple example: if $s(t)$ represents the position of an object at time t , then $s'(t)$, the derivative of position with respect to time, is the object's instantaneous velocity. Similarly, the derivative of velocity is acceleration. This chain of derivatives forms the basis for many physics-related word problems.

Identifying Key Variables and Relationships

The first, and arguably most critical, step in solving any derivative word problem is to thoroughly read and understand the problem statement. This involves:

1. **Identifying the unknown:** What are you being asked to find? Is it a maximum value, a minimum value, a specific rate, or a time when a certain condition is met?
2. **Identifying the given information:** What quantities and their relationships are provided?
3. **Defining variables:** Assign clear symbols to represent the quantities involved. For instance, V for volume, A for area, t for time, P for profit, C for cost.
4. **Formulating an equation:** Translate the relationships between these variables into a mathematical equation. This is often the most challenging part, requiring a solid understanding of geometry, algebra, or other relevant mathematical principles.

The Role of Implicit Differentiation

Many word problems involve relationships between variables where it's difficult or impossible to express one variable solely in terms of the other. This is where implicit differentiation becomes invaluable. When variables are intertwined in an equation (e.g., $x^2 + y^2 = r^2$), implicit differentiation allows us to find dy/dx by differentiating both sides of the equation with respect to x , treating y as a function of x and using the chain rule.

Common Types of Derivative Word Problems and Their Solutions

Derivative word problems can be broadly categorized, each requiring a slightly different approach. Understanding these categories can help you anticipate the problem-solving strategy.

1. Optimization Problems: Finding Maxima and Minima

Optimization problems are perhaps the most ubiquitous type of derivative word problem. They involve finding the maximum or minimum value of a quantity that depends on one or more variables. This could be maximizing profit, minimizing cost, finding the dimensions of a container that yield the largest volume, or determining the fastest route.

Strategy for Optimization Problems:

1. **Understand the Objective:** Clearly identify what quantity needs to be maximized or minimized (e.g., Volume V , Area A , Profit P).

2. **Set up the Primary Equation:** Write an equation that expresses the quantity to be optimized in terms of your variables.
3. **Set up the Constraint Equation(s):** Identify any limitations or conditions given in the problem. These will usually allow you to express one variable in terms of another, reducing the primary equation to a function of a single variable.
4. **Substitute:** Substitute the expression from the constraint equation into the primary equation.
5. **Differentiate:** Find the derivative of the resulting single-variable function.
6. **Find Critical Points:** Set the derivative equal to zero and solve for the variable. Also, consider any endpoints of the domain if applicable.
7. **Apply the Second Derivative Test (or First Derivative Test):** Use the second derivative to determine if the critical point corresponds to a local maximum or minimum. If $f''(c) < 0$, it's a maximum. If $f''(c) > 0$, it's a minimum. If $f''(c) = 0$, the test is inconclusive.
8. **Answer the Question:** Plug the value(s) of the variable back into the original equations to find the required maximum or minimum value and the corresponding dimensions or conditions.

Example Optimization Problem:

A farmer wants to enclose a rectangular field with 1000 meters of fencing. One side of the field is along a river and does not need fencing. What dimensions of the field will maximize the area?

Solution:

1. Let l be the length of the field parallel to the river and w be the width perpendicular to the river.
2. **Primary Equation (Area):** $A = l * w$
3. **Constraint Equation (Fencing):** $l + 2w = 1000$ (since one side of length l doesn't need fencing).
4. **Substitute:** From the constraint, $l = 1000 - 2w$. Substitute this into the area equation: $A(w) = (1000 - 2w) * w = 1000w - 2w^2$.
5. **Differentiate:** $A'(w) = 1000 - 4w$.
6. **Find Critical Points:** Set $A'(w) = 0$: $1000 - 4w = 0 \Rightarrow 4w = 1000 \Rightarrow w = 250$ meters.
7. **Second Derivative Test:** $A''(w) = -4$. Since $A''(250) = -4 < 0$, this corresponds to a maximum.
8. **Answer:** If $w = 250$ m, then $l = 1000 - 2(250) = 1000 - 500 = 500$ m. The dimensions that maximize the area are 500 meters by 250 meters.

2. Related Rates Problems: Rates of Change of Interdependent Quantities

Related rates problems deal with situations where multiple quantities are changing with time, and their rates of change are interconnected. The key is to find how fast one rate is changing based on the rate of change of another related quantity. These problems often involve geometric shapes and their dimensions changing simultaneously.

Strategy for Related Rates Problems:

1. **Draw a Diagram:** Visualize the scenario and label all relevant quantities.
2. **Identify Given Rates and the Rate to Find:** Clearly state what rates are known (e.g., dx/dt , dV/dt) and what rate you need to calculate (e.g., dy/dt , dA/dt).
3. **Write an Equation Relating the Quantities:** Establish an equation that connects the variables whose rates are involved. This is often based on geometric formulas or other physical principles.
4. **Differentiate Implicitly with Respect to Time (t):** Differentiate both sides of the equation with respect to time, remembering to use the chain rule for each variable that depends on time (e.g., $d/dt (x^2) = 2x * dx/dt$).
5. **Substitute Known Values:** Plug in the given rates and any other known values at the specific moment in time.
6. **Solve for the Unknown Rate:** Algebraically solve the resulting equation for the rate you need to find.

Example Related Rates Problem:

A ladder 10 feet long rests against a vertical wall. If the bottom of the ladder slides away from the wall at a rate of 2 ft/sec, how fast is the top of the ladder sliding down the wall when the bottom of the ladder is 6 feet from the wall?

Solution:

1. Let x be the distance from the bottom of the ladder to the wall, and y be the height of the top of the ladder on the wall. The ladder has a constant length of 10 feet.
2. **Given:** $dx/dt = 2$ ft/sec. We need to find dy/dt when $x = 6$ ft.
3. **Equation:** Using the Pythagorean theorem, $x^2 + y^2 = 10^2$.
4. **Differentiate with respect to t:** $2x * dx/dt + 2y * dy/dt = 0$.
5. **Find y when x = 6:** $6^2 + y^2 = 10^2 \Rightarrow 36 + y^2 = 100 \Rightarrow y^2 = 64 \Rightarrow y = 8$ ft.
6. **Substitute known values:** $2(6)(2) + 2(8) * dy/dt = 0$.
7. **Solve for dy/dt:** $24 + 16 * dy/dt = 0 \Rightarrow 16 * dy/dt = -24 \Rightarrow dy/dt = -24/16 = -3/2$ ft/sec.

The top of the ladder is sliding down the wall at a rate of 1.5 ft/sec.

3. Velocity, Acceleration, and Motion Problems

These problems are a direct application of derivatives to physics, specifically the study of motion. Position, velocity, and acceleration are intimately related through differentiation.

Key Relationships:

1. If $s(t)$ is the position function, then velocity is $v(t) = s'(t)$.
2. Acceleration is the derivative of velocity: $a(t) = v'(t) = s''(t)$.
3. Conversely, velocity is the integral of acceleration, and position is the integral of velocity.

Common Questions:

1. When is an object at rest? (When $v(t) = 0$)
2. When is an object moving in the positive direction? (When $v(t) > 0$)
3. When is an object moving in the negative direction? (When $v(t) < 0$)
4. When is the object speeding up or slowing down? (Speeding up if velocity and acceleration have the same sign; slowing down if they have opposite signs).
5. What is the maximum height reached by a projectile? (This is an optimization problem where the vertex of the parabolic trajectory represents the maximum height, and can be found by setting the velocity $v(t)$ to zero).

Example Motion Problem:

The position of a particle is given by $s(t) = t^3 - 6t^2 + 5$, where s is in meters and t is in seconds. Find the velocity and acceleration of the particle, and determine when the particle is at rest.

Solution:

1. **Velocity:** $v(t) = s'(t) = 3t^2 - 12t$.
2. **Acceleration:** $a(t) = v'(t) = s''(t) = 6t - 12$.
3. **Particle at Rest:** Set $v(t) = 0$: $3t^2 - 12t = 0 \Rightarrow 3t(t - 4) = 0$. This gives $t = 0$ seconds or $t = 4$ seconds.

The particle is at rest at $t = 0$ and $t = 4$ seconds.

4. Marginal Analysis in Economics

In economics, derivatives are used to analyze the effect of small changes in one variable on another. The concept of marginal cost, marginal revenue, and marginal profit is directly derived from the derivative of the total cost, total revenue, and total profit functions, respectively. Marginal means "the rate of change of."

Key Concepts:

1. **Marginal Cost (MC):** The derivative of the total cost function $C(q)$ with respect to quantity q . It approximates the cost of producing one additional unit.
2. **Marginal Revenue (MR):** The derivative of the total revenue function $R(q)$ with respect to quantity q . It approximates the revenue from selling one additional unit.
3. **Marginal Profit (MP):** The derivative of the total profit function $P(q)$ with respect to quantity q . It approximates the profit from selling one additional unit.

Profit is maximized when marginal revenue equals marginal cost ($MR = MC$), which is equivalent to setting the derivative of the profit function ($P'(q) = MR - MC$) to zero.

Example Economic Problem:

The cost function for a company is $C(q) = 0.01q^2 + 10q + 1000$, where q is the number of units produced. Find the marginal cost when 100 units are produced.

Solution:

1. **Marginal Cost:** $MC(q) = C'(q) = 0.02q + 10$.
2. **Marginal Cost at $q = 100$:** $MC(100) = 0.02(100) + 10 = 2 + 10 = 12$.

The marginal cost of producing the 101st unit is approximately \$12.
